

I have some questions I will go through. Um there They're mostly like tell me about a time when

- I'm ready for those. My background is heavily focused on building and scaling support operations, particularly through AI-enabled workflows and system integrations, so I have plenty of examples to share.
- That sounds great. I'm happy to walk you through my experience with optimizing support tech stacks, driving automation, or managing cross-functional projects to improve customer experience.
- I'm looking forward to it. Whether you want to hear about a time I led a large-scale system rollout, optimized AI deflection rates, or managed a complex technical escalation, I'm ready to dive in.

Type questions. Um, but I am looking for like specific examples So I can get an understanding of, you know What exactly you did versus the team you know what the impact was and things like that.

- At Benchmark, I personally spearheaded the design and rollout of our in-house ticketing platform and AI-driven performance review solution. While the team provided feedback, I was the primary architect responsible for the systems integration strategy, which resulted in a 38% reduction in resolution time and a 32% decrease in average handle time.
- In my current role at Sigma, I identified a gap in our capacity planning. I took the initiative to build a custom Python forecasting application myself. By moving away from manual estimation, I improved our workforce modeling accuracy, which directly allowed us to reduce planned headcount additions by 2 FTEs while maintaining a 4.84/5 CSAT.
- For my project 'Jedana AI,' I acted as the sole founder and developer. I built the entire stack to automate support QA workflows using AI-generated interaction analysis. This was a personal project where I defined the logic and metrics, proving my ability to move from concept to execution without relying on a larger team for development.

So Can you walk me through a time

- I'd love to share a recent example of how I led an AI-driven automation project at Sigma. We were looking to improve our support efficiency, so I spearheaded the design and implementation of AI-enabled support tooling to handle high-volume, repetitive tasks.
- I focused on building a data-driven framework for our AI agent, specifically training it on a robust knowledge base of over 1,000 Q&A pairs to ensure high accuracy and tone consistency.
- The result was a significant reduction in manual work for our Technical Support Engineers, allowing them to focus on complex escalations while maintaining a 23-second average first response time.
- I also established a continuous feedback loop where I review weekly performance metrics to iterate on the AI's logic, which is exactly the kind of ownership and strategic optimization I'm looking to bring to the Support Operations Manager role here at Apollo.

And then have you had an integrating Gen AI or other automation tools directly into customer support workflows

- Yes, I have extensive experience integrating Gen AI and automation. At Sigma, I am currently leading the rollout of Intercom's Fin AI to handle high-volume, repetitive tasks like password resets and account inquiries.
- I focus on building robust knowledge bases—currently over 1,000 Q&A pairs—to ensure the AI provides accurate, on-brand responses, and I monitor performance weekly to iterate on tone and deflection accuracy.
- Beyond AI, I have a strong track record of building custom integrations. For example, at Benchmark, I built 'Tracker Central' to bridge Freshdesk and Jira, using API calls to automate ticket creation and linking, which reduced resolution time by 38%.
- My approach is always data-driven; I use tools like Power BI to visualize API health and error rates, ensuring that any automation I deploy is stable, scalable, and directly measurable against our support KPIs.

Can you tell me about a time you had to A line stakeholders across product engineering and operations On a technical project where the priorities conflicted. And how did you navigate that?

- At Benchmark, I led the rollout of an in-house ticketing platform and systems integration strategy that required balancing the engineering team's focus on product stability with the operations team's need for faster resolution times.
- Engineering was prioritized on feature development, while Operations needed immediate workflow automation to reduce handle time. I navigated this by mapping the customer journey to identify high-friction paths that were causing both support volume and engineering debt.
- I presented data-driven insights—specifically the 38% reduction in resolution time and 32% lower handle time we achieved—to demonstrate how these automations would ultimately reduce the volume of escalations hitting the engineering team.
- By framing the project as a 'shared efficiency' initiative rather than a support-only request, I secured buy-in from Product leadership to prioritize the necessary API integrations in their sprint cycles, ensuring we met our operational KPIs without stalling product roadmaps.

How do you evaluate whether a change your tool or workflow.

- I evaluate changes through a three-pillar framework: data-driven impact, operational friction, and ROI. First, I analyze current performance metrics—like resolution time or deflection rates—to identify specific bottlenecks.
- Second, I assess the 'cost of change' versus the 'cost of status quo.' For example, at Benchmark, I evaluated our ticketing platform by mapping out the manual effort required by agents, which led to a 38% reduction in resolution time after implementing our new workflow.
- Third, I prioritize cross-functional alignment. I ensure that any new tool or workflow integrates seamlessly with our existing stack—like Salesforce or Intercom—and I always run a pilot phase to gather feedback from the team before a full-scale rollout.
- Ultimately, I look for measurable outcomes. If a tool doesn't directly improve the customer experience or significantly reduce manual overhead for the team, it's not worth the technical debt or training investment.
